Opal

Opal is a hydrated amorphous form of silica ($\text{SiO}_2 \cdot n \text{H}_2\text{O}$); its water content may range from 3 to 21% by weight, but is usually between 6 and 10%. Because of its amorphous character, it is classed as a mineraloid, unlike crystalline forms of silica, which are classed as minerals.

Opal - Wikipedia

Mineralogically, opal is a hydrous silicon dioxide with a chemical composition of $\text{SiO}_2 \cdot n\text{H}_2\text{O}$. It is amorphous, without a crystalline structure, and without a definite chemical composition (it contains a variable amount of water, as shown by the "n" in its chemical composition). Therefore opal is a " mineraloid " rather than a " mineral."

Amazon.com: opal ring

Opal, silica mineral extensively used as a gemstone, a submicrocrystalline variety of cristobalite. In ancient times opal was included among the noble gems and was ranked second only to emerald by the Romans. In the Middle Ages it was supposed to be lucky, but in modern times it has been regarded as unlucky.
